Jaundice is usually a minor presentation of Kawasaki Disease (KD) and includes hepatobiliary disfunction or gallbladder hydrops. We are reporting 2 cases of unusual Kawasaki Disease with fever and jaundice as the initial presentation. In one patient, other signs typical of the Kawasaki disease occurred a few days later and permitted diagnosis, while in the other there were no typical signs of Kawasaki Disease. Both patients improved after given intravenous immunoglobulin. Echocardiography revealed heart abnormalities in both patients. Our case report suggests that KD should be added to the differential diagnosis of a febrile and icteric young patient.
